Capturing appearance of material with respect to illumination and viewing directions is crucial to achieve realistic visual experience in virtual environments. The capturing process is time demanding or requires a specific shape of the captured material. Therefore, we propose a method of such a data

Abstract

reconstruction from very sparse measurements, whose placement allows for continuous and fast acquisition, from which can benefit future acquisition setups. The proposed approach shows a promising performance in terms of whole data-space reconstruction speed and visual quality.

Problem Definition

Realistic appearance of materials can be captured only using view- & illumination dependent appearance data:

Standard approaches:

- uniform sampling → time demanding,
- or requires specific sample's shape.

Applicable appearance representations: BRDF, SVBRDF, Apparent BRDF, BTF.

The Proposed Method

Sparse ABRDF sampling and reconstruction:

- (b) using 8 continuous slices in 4 subspaces (fixed elevation angles),
- (c) interpolation of missing data in subspaces,
- (d) interpolation of missing subspaces (RBF).

- Subspace (θ_i/θ_v) represented by axial slice s_A (red) and diagonal slice s_D (blue):

$$s_A(\varphi_i) = B(\theta_i, \theta_v, \varphi_i, \varphi_v = \varphi_i + \alpha),$$

$$s_D(\varphi_v) = B(\theta_i, \theta_v, \varphi_i = 2\pi - \varphi_v + \alpha, \varphi_v).$$

- s_A rotation of the sample below fixed light and sensor (anisotropic behavior)
- s_D mutually opposite movement of the light and sensor (specular highlights)

- Subspace reconstruction from the slices:

$$v(\varphi_i, \varphi_v) = s_A(\varphi_{i,R}) + s_D(\varphi_{v,R}),$$

$$\begin{bmatrix} \varphi_{i,R} \\ \varphi_{v,R} \end{bmatrix} = \begin{bmatrix} \cos \pi/4 & -\sin \pi/4 \\ \sin \pi/4 & \cos \pi/4 \end{bmatrix} \begin{bmatrix} \varphi_i \\ \varphi_v \end{bmatrix}.$$

- Values normalization to original slices range:

$$\hat{B}(\theta_i, \theta_v, \varphi_i, \varphi_v) = v(\varphi_i, \varphi_v) \cdot (M - m) + m,$$

$$m = \min(s_A \cup s_D) \quad M = \max(s_A \cup s_D),$$

where: v is normalized to range $[0,1]$.

Tests and Results

- Anisotropic subspaces reconstruction from slices (view & illumination elevations 75°):

- experiments (below ↓): original ABRDF and its complete reconstruction using 204 samples (8 slices) + difference in CIE ΔE /RMSE/PSNR.

Method's Key Features

- fast ABRDF reconstruction from sparse samples (204 samples used) $\approx 1s$,
- intuitive continuous sampling for fast measurement of slices,
- no input data restriction (anisotropic, non-reciprocal, HDR, specular),
- arbitrarily dense angular data modeling,
- contribution to future development of simple, inexpensive acquisition setups of illumination- & view-dependent data.
